

Sexual and Reproductive Health (SRH) Services Analysis

SRH Analysis: A data analysis was carried to assess utilization of SRH services and associated factors among adolescents at four general hospitals in Abuja.

Data Collection: Data were collected using Kobo toolbox.

Analysis:

The collected data were extracted and analyzed in Excel. A total of seven responses were received, and the analysis compared the number of males and females who accessed the services.

The report shows that the total number of females who accessed condoms is 540, compared to the number of males, which is 500.

Additionally, the report indicates that the percentage of females who accessed counseling and testing services is higher at 62% compared to the percentage of males at 38%.

Conclusion:

We can conclude that the services were utilized and majority of the those who utilized the services were females. However, the numbers are still low.

Recommendation:

More awareness programs need to be created, and people need to be sensitized on the use of the services, especially males. This is necessary to achieve the objectives of the program, which include the reduction of unwanted pregnancies, unsafe abortions, sexually transmitted infections, including HIV/AIDS, and all forms of sexual violence and coercion.
